OBJECTIVES

- Developing gas-phase biosensor systems for quantitative monitoring of breath acetone
- Screening diabetes mellitus (DM) patients through assessment of lipid metabolism via breath

Significance of acetone measurement

Concentration ranges of acetone

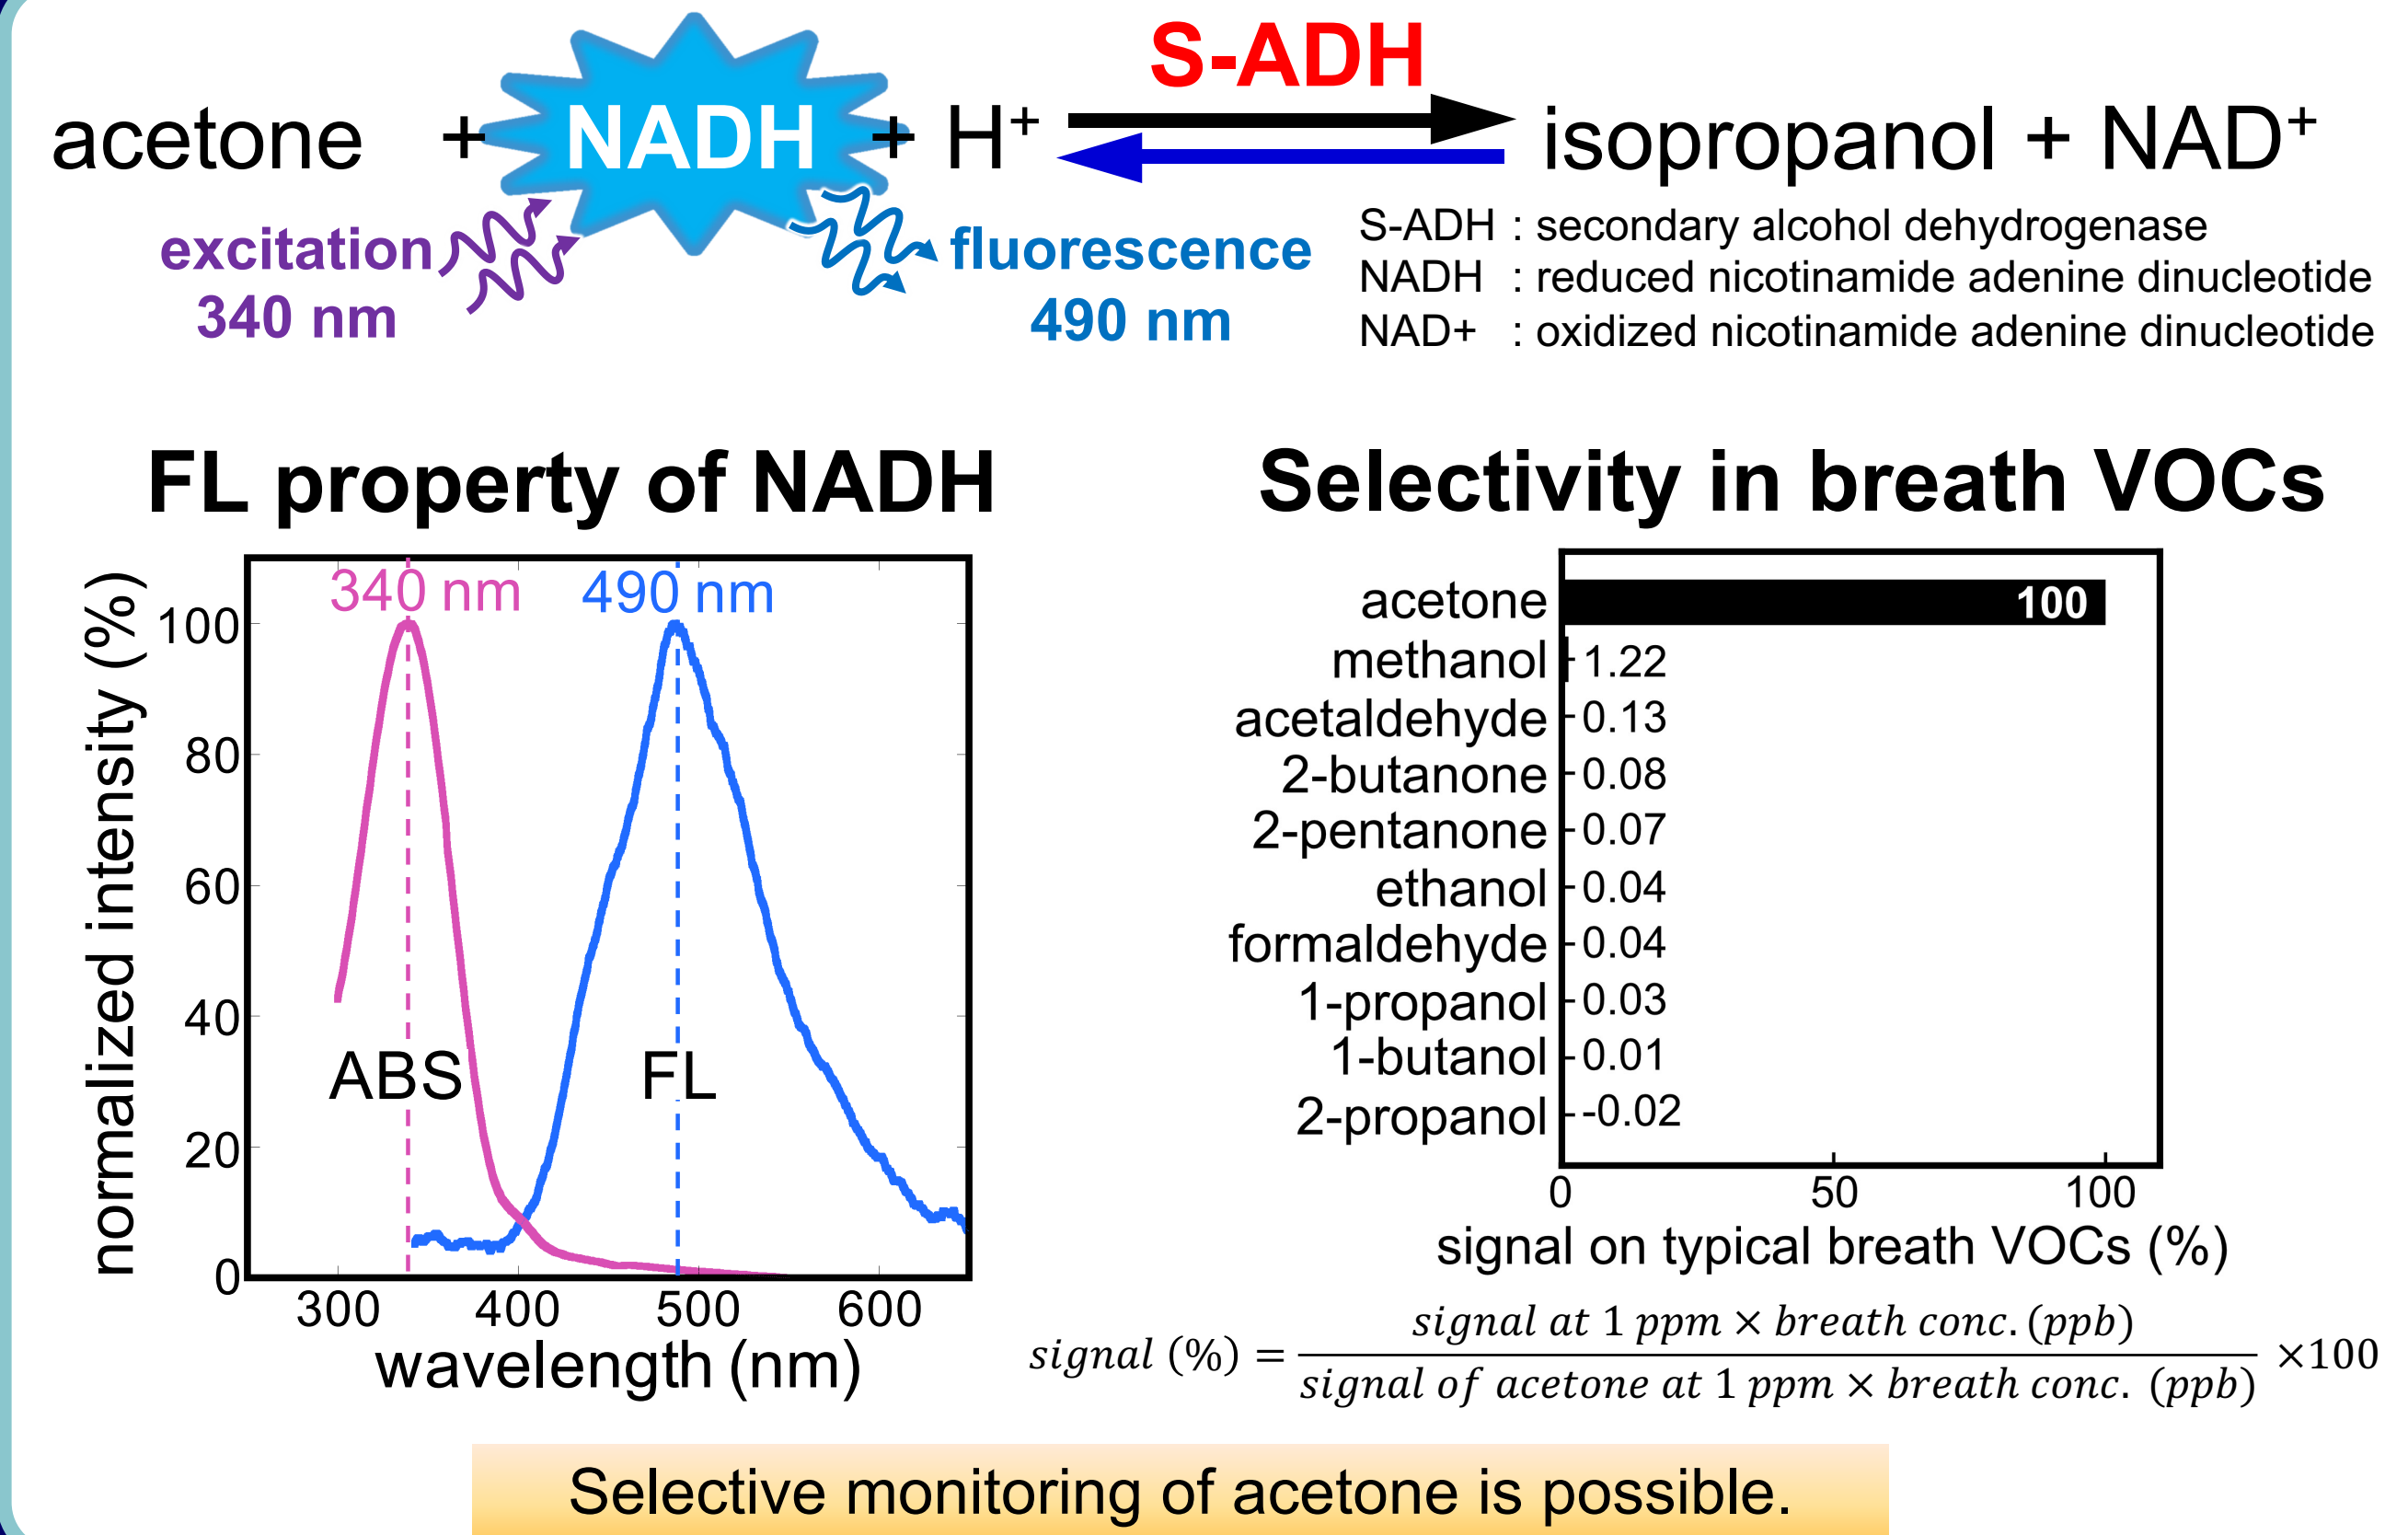

Conventional methods

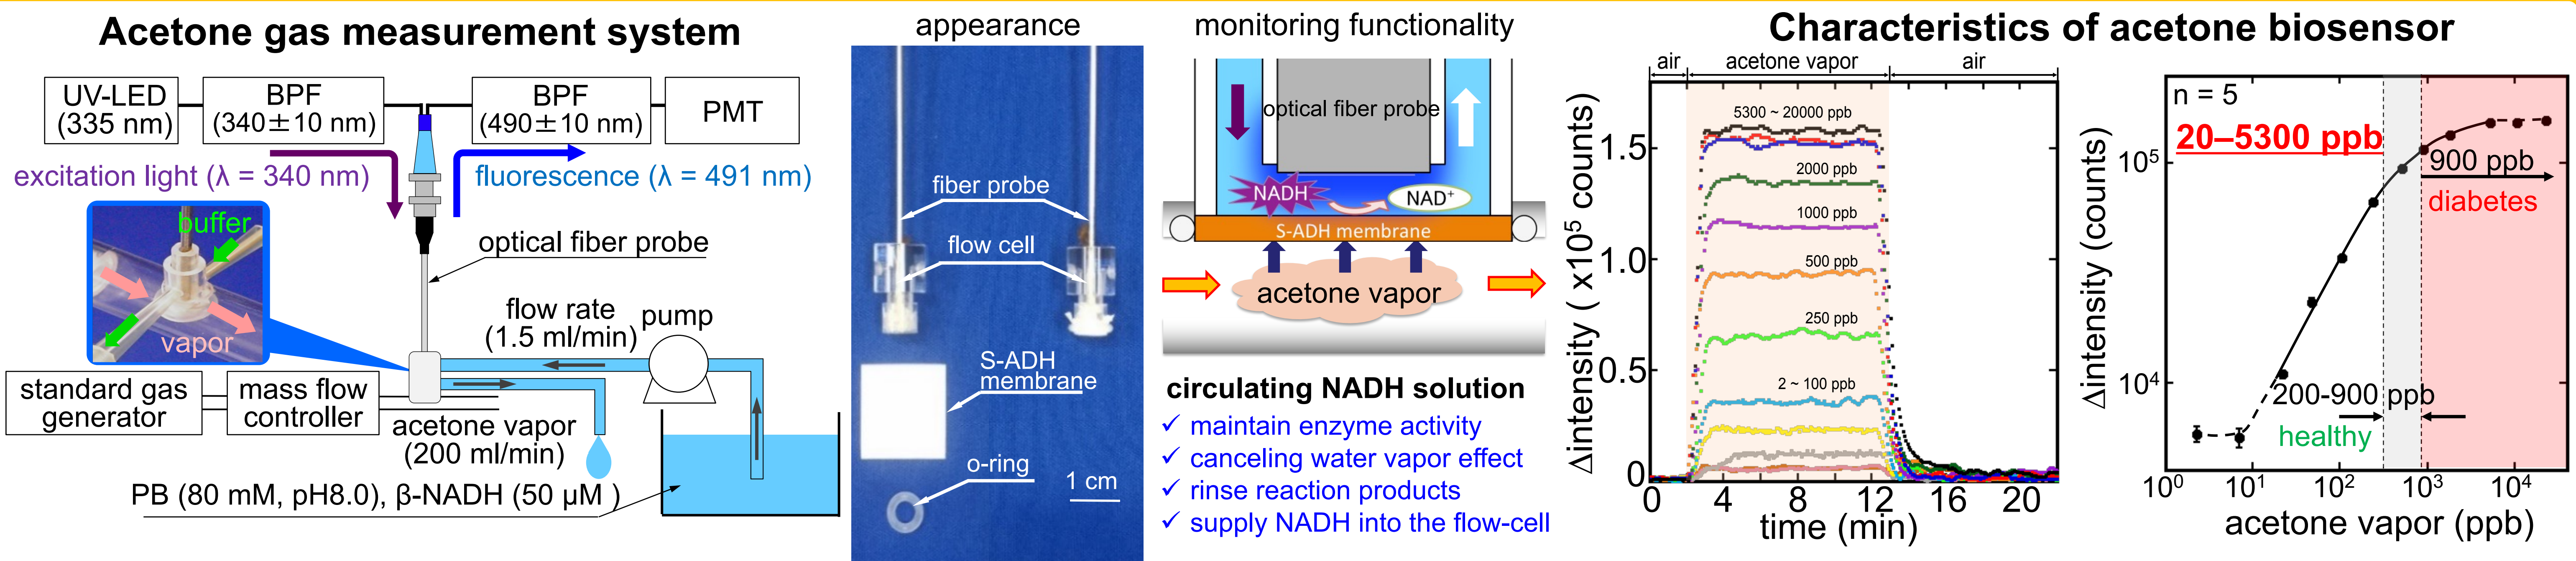

Method	Characteristics
GC-MS	○ sensitivity, selectivity × continuity
semiconductor	○ continuity, convenience × selectivity

Require continuous, sensitive & selective sensor

Bio-fluorometric sensing of acetone

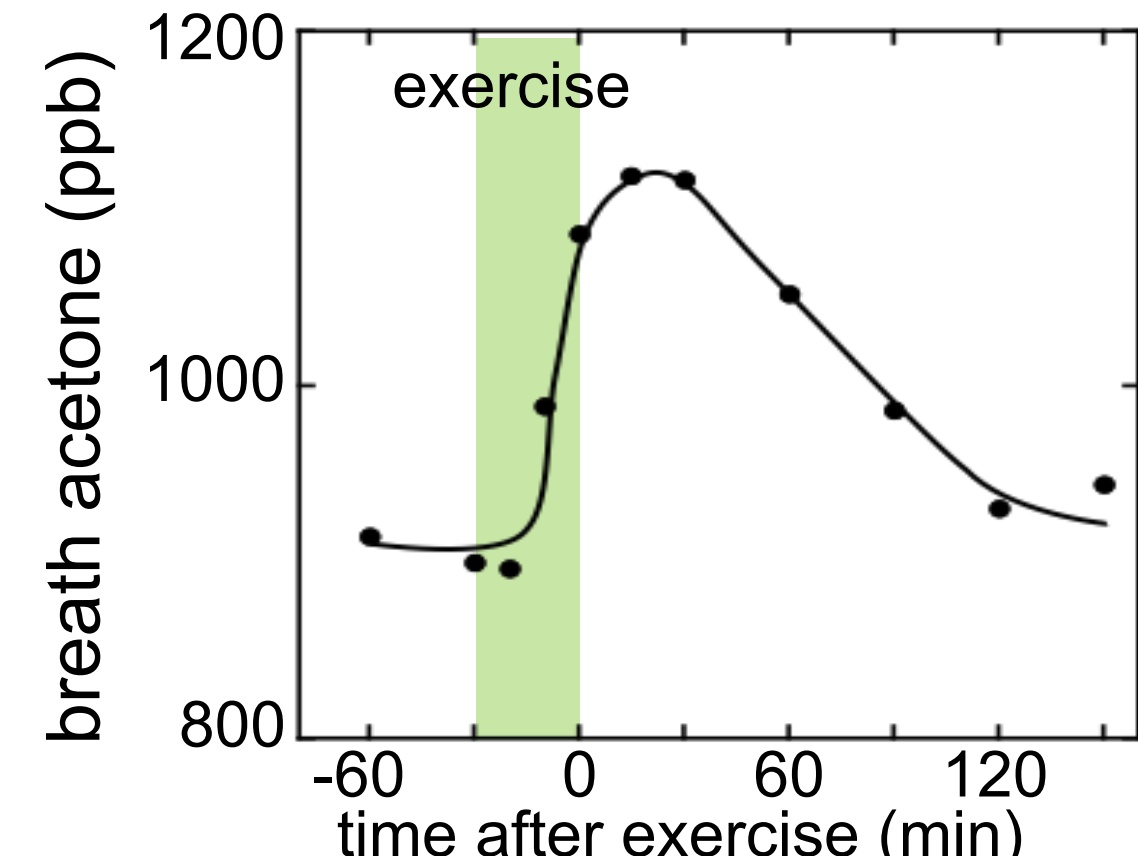

Fiber-optic acetone gas sensor for screening of DM via breath monitoring

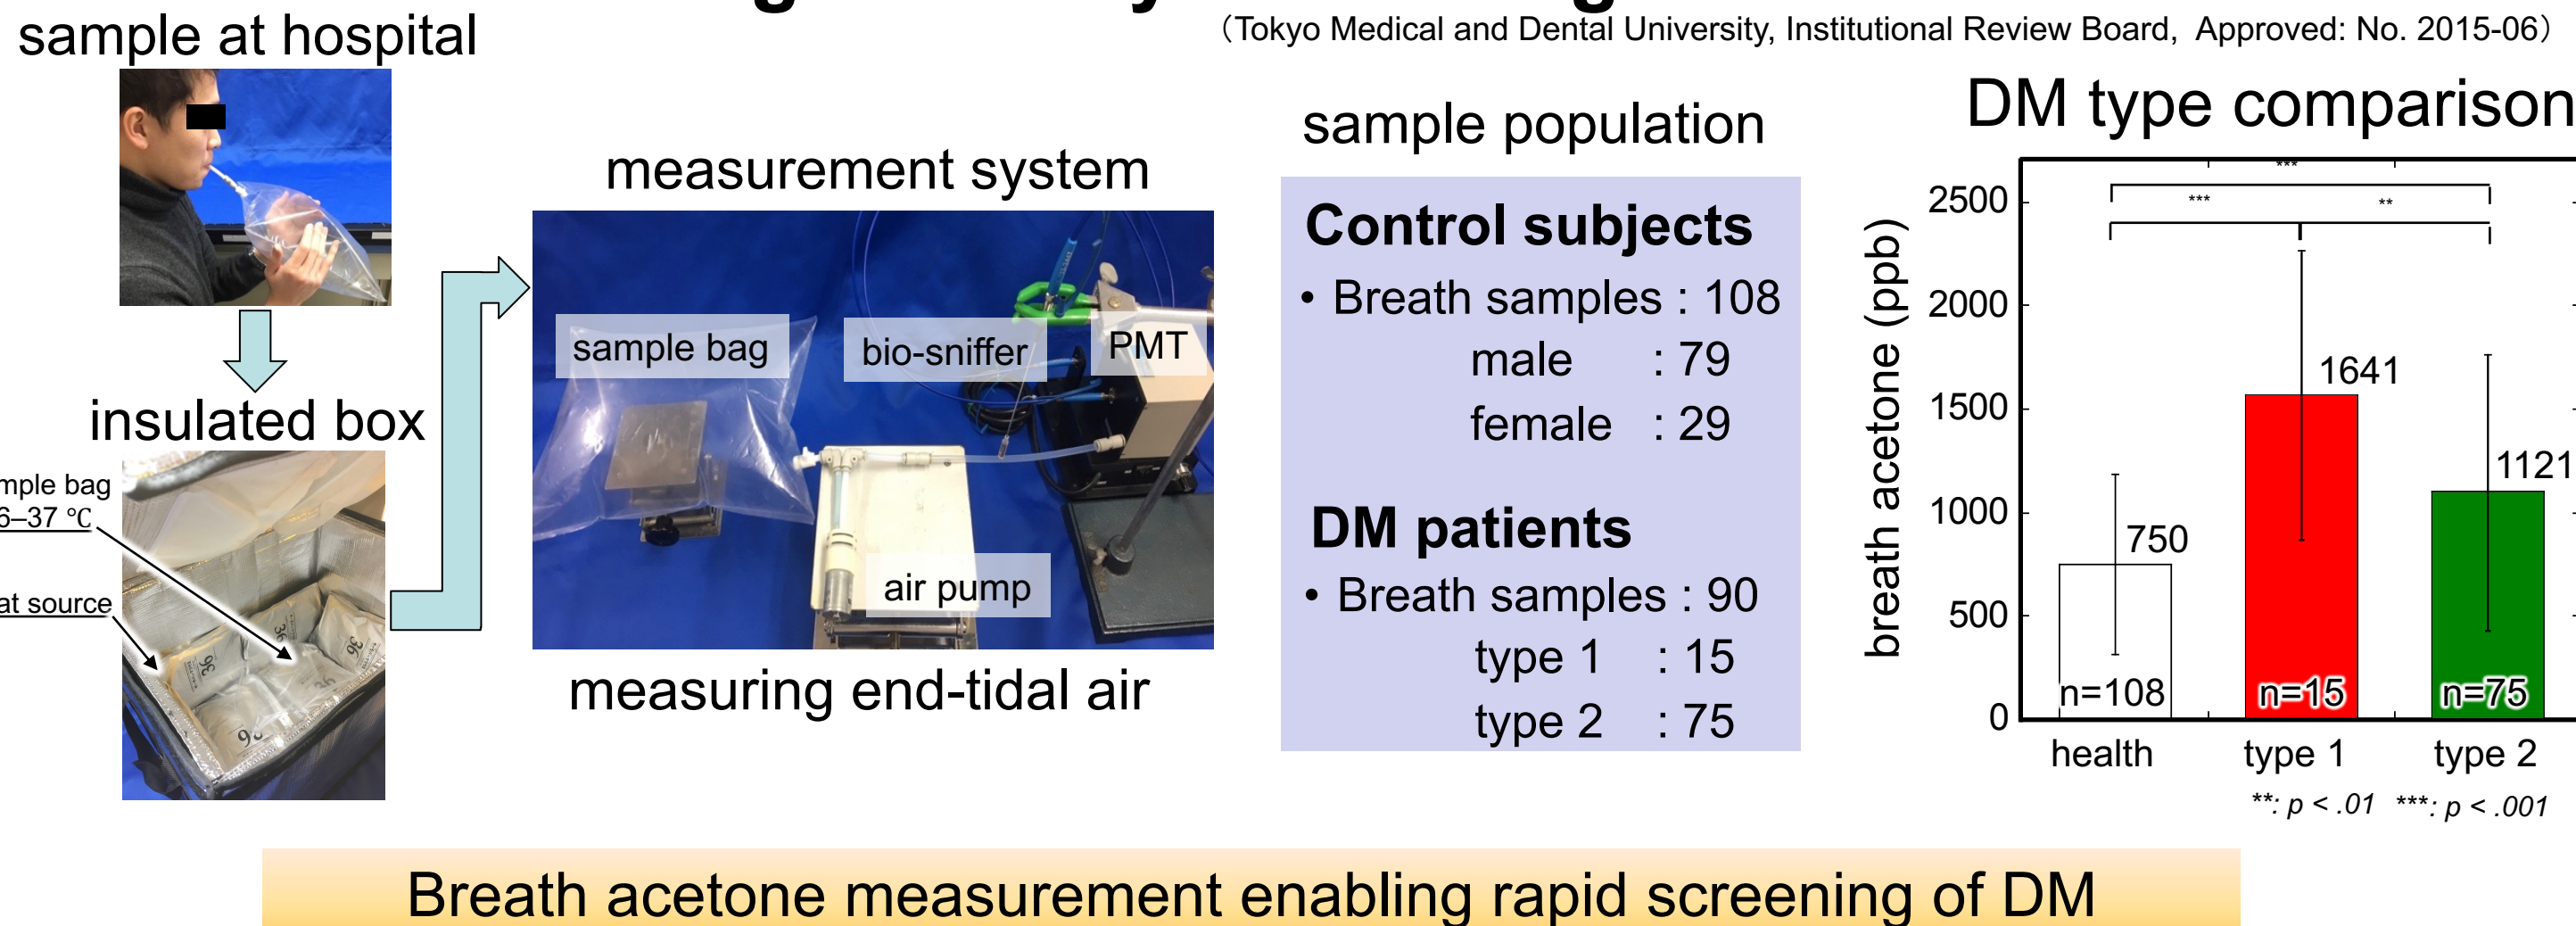

Evaluation of lipid metabolism

Time course of breath acetone

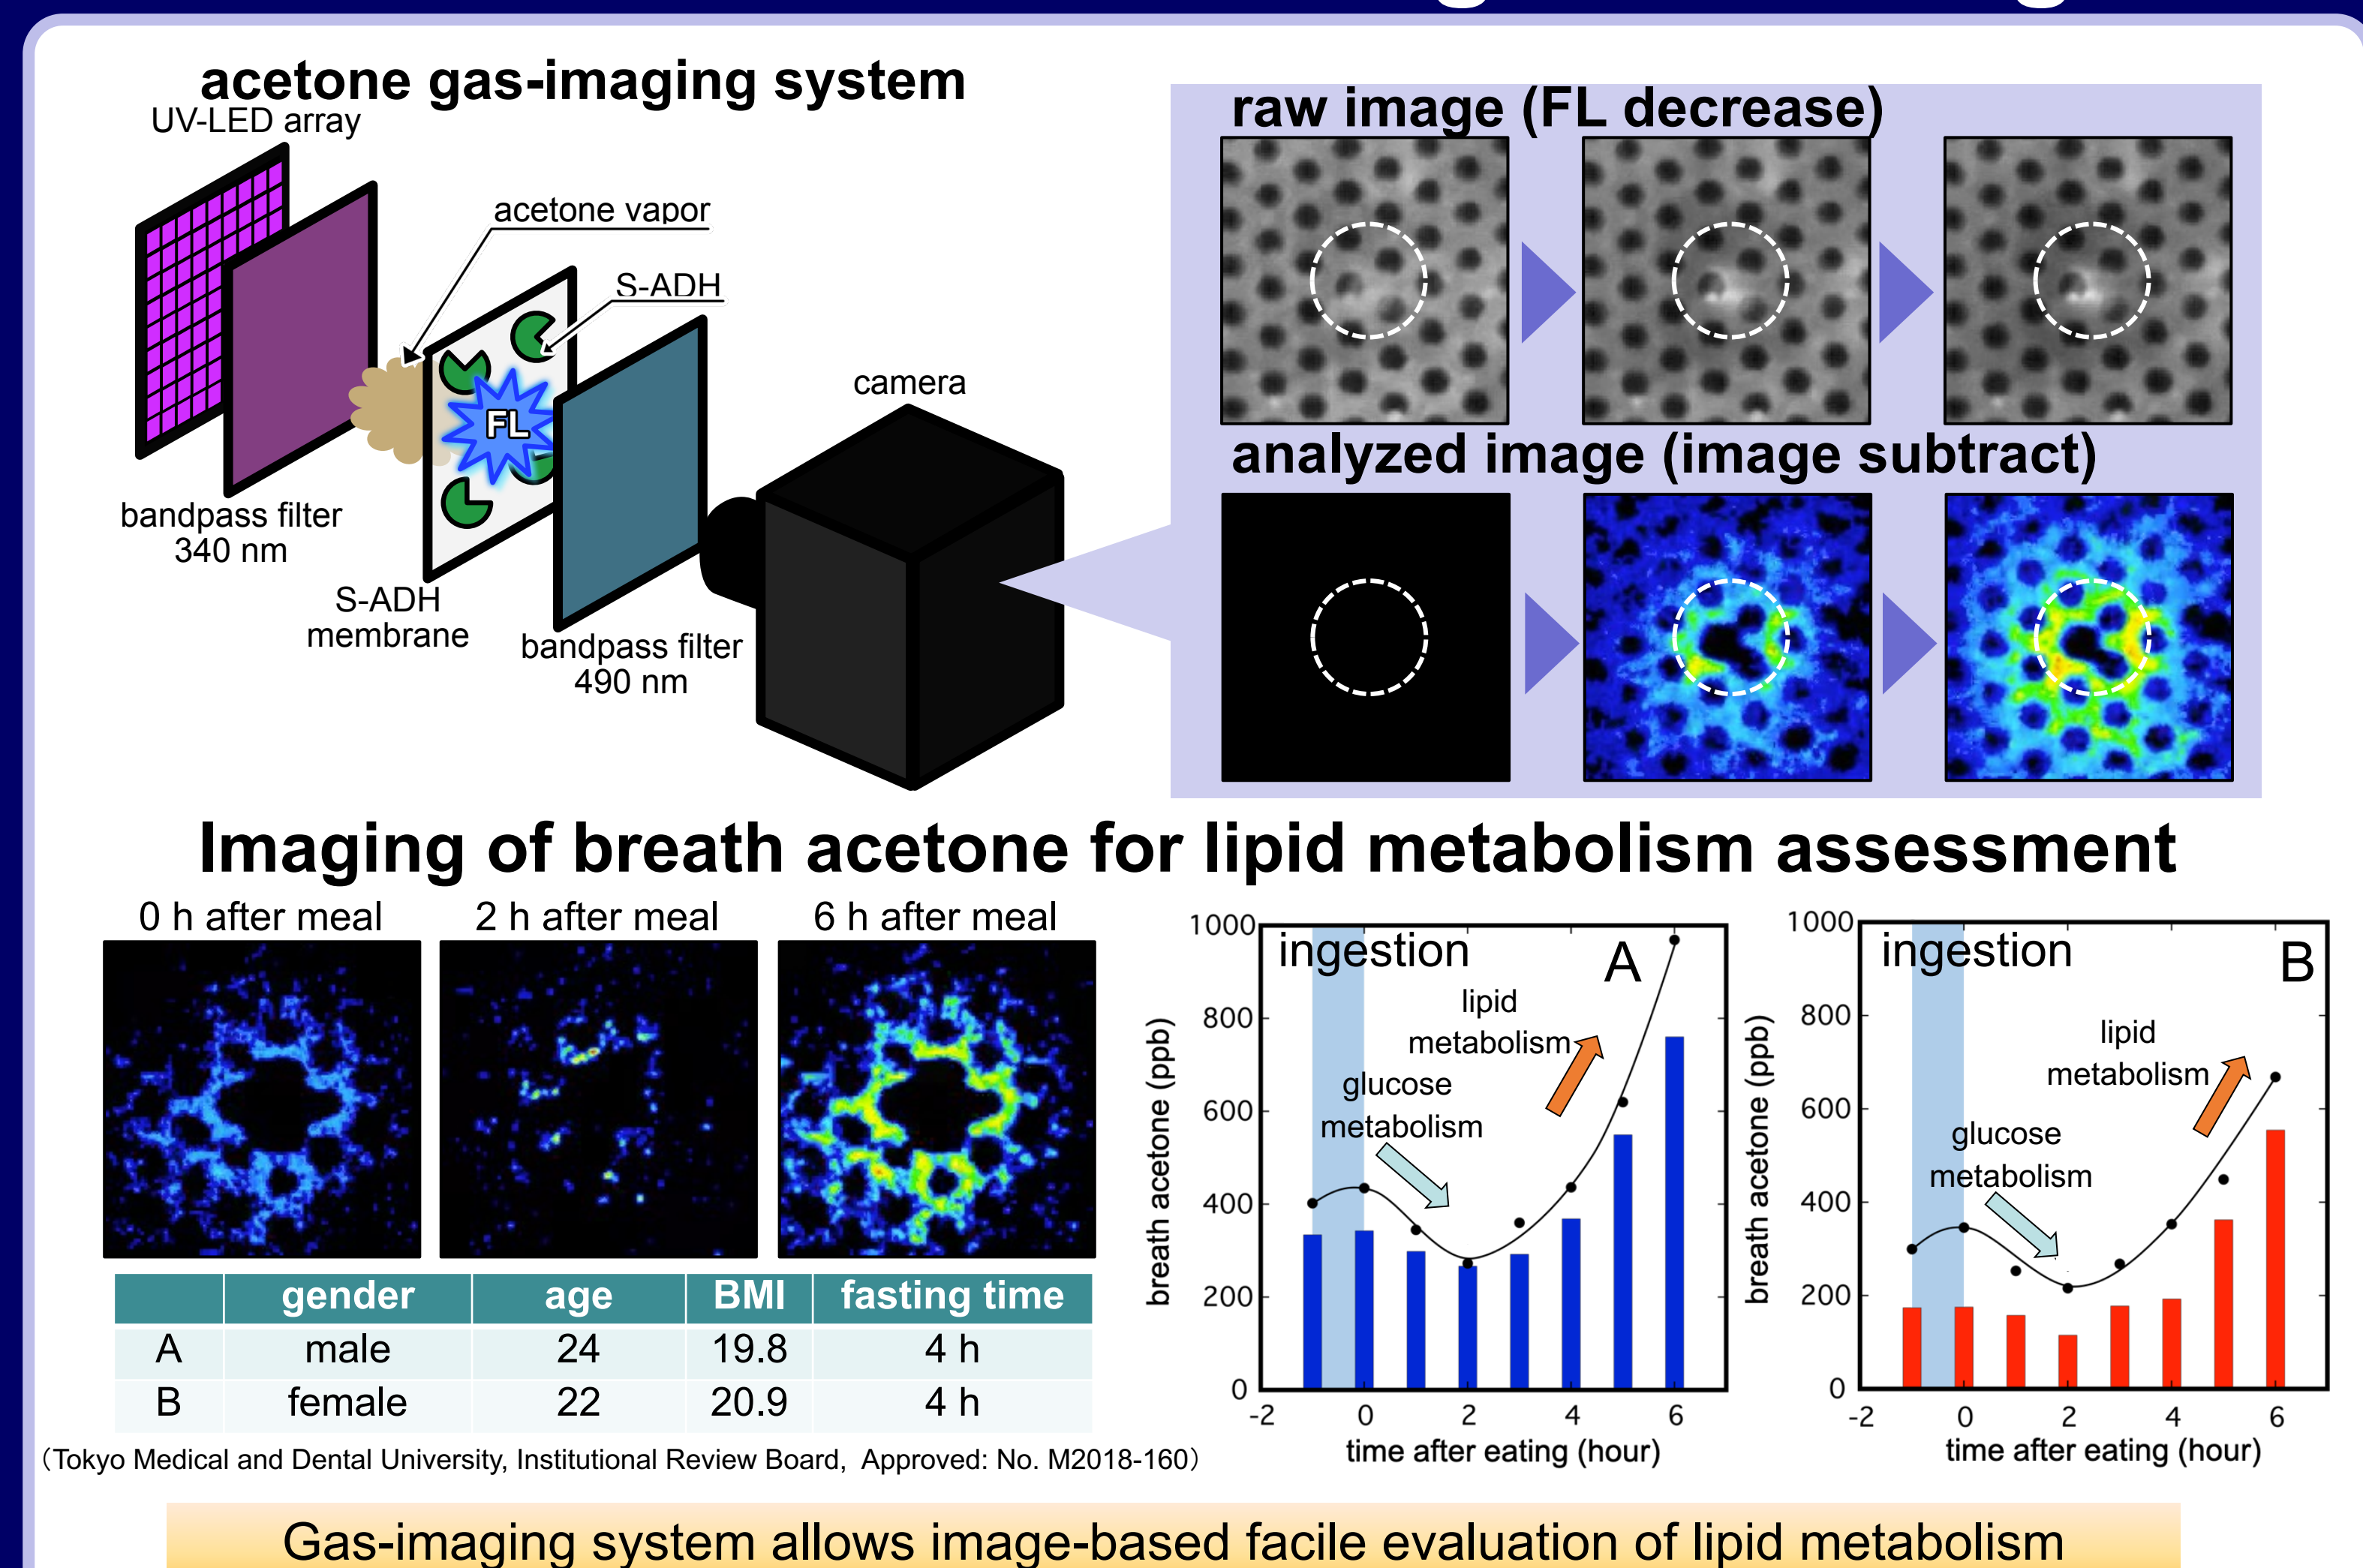

Real-time monitoring of lipid metabolism through breath acetone

Screening of DM by measuring breath acetone

Breath acetone measurement enabling rapid screening of DM

New "dimension" of gas sensing

Gas-imaging system allows image-based facile evaluation of lipid metabolism

SUMMARY

- The high-sensitive and high-selective acetone bio-sniffer with flow-cell was developed.
calibration range: 20–5300 ppb, response time: 35–70 s, reproducibility: 97.3%
- Spatiotemporal change of acetone gas was imaged by bio-fluorometric gas-imaging system.
calibration range: 50–2000 ppb, response time: 20 s
- Real-time monitoring of lipid metabolism and DM classification were demonstrated.
